Abstract
In this paper we introduce the language Golog+HTN\textsuperscript{TI} for specifying control using procedural and HTN-based constructs together with deadlines and time restrictions. Our language starts with features from GOLOG and HTN and extends them so that we can deal with actions with duration by being able to specify time intervals between the start (or end) of an action (or a program) and the start (or end) of another action (or program). We then discuss an off-line interpreter based on the answer set planning paradigm such that the answer sets of the logic program have a one-to-one correspondence with the traces of the Golog+HTN\textsuperscript{TI} specification.

Introduction and Motivation
GOLOG (Levesque et al. 1997) is an Algol-like logic programming language for agent programming, control, and execution. It is based on the situation calculus theory of actions (Reiter 2000). GOLOG has been primarily used as a programming language for high-level agent control in dynamical environments (see e.g. (Burgard et al. 1998)). Some of the ways GOLOG can be extended are: (a) adding new program constructs (and providing the semantics for these constructs thereafter); or (b) adapting the language to an extension of situation calculus; or (c) combining (a) and (b). The first approach to extending GOLOG has been taken by (De Giacomo, Lespérance, & Levesque 2000; Baral & Son 1999) where various new constructs such as concurrency, interrupts, prioritized interrupts, or partial ordering are added to GOLOG. The other approaches can be seen in (Reiter 2001; Grosskreutz & Lakemeyer 2000; Boutilier et al. 2000) where continuous changes, durative actions, or stochastic actions are considered. In these extensions, time instances are introduced for specifying when an action (or a program) should be executed; in (Grosskreutz & Lakemeyer 2000), it is argued that the explicit specification of time in GOLOG programs – similar to what is used in (Reiter 2001) (also in (Boutilier et al. 2000)) – is not adequate for specifying event-driven behaviors and cc-Golog is proposed to address this problem. However, none of the constructs in cc-Golog allows us to express a simple behavior like “action \(a\) should start its execution within 3 units of time after action \(b\) starts its execution” because the language forces actions to happen as soon as possible, which – given that both \(a\) and \(b\) are executable at the time 0 – will not allow us to consider “\(a\) starts at 0 and \(b\) starts at 1” as an acceptable trajectory even though it satisfies the stated constraint.

In this paper, we investigate the introduction of actions with duration into the framework proposed in (Son, Baral, & McIlraith 2001) in which not only GOLOG-constructs such as sequence, while-loop, if-then-else, etc. but also HTN-based constructs such as the partial ordering and temporal constraints are allowed. This leads to a language\(^1\), called Golog+HTN\textsuperscript{TI}, that generalizes GOLOG-based and HTN-based specifications with time intervals. Our language differs from the extensions of GOLOL in (Reiter 2001; Grosskreutz & Lakemeyer 2000; Boutilier et al. 2000) in that it includes different HTN-based constructs such as partial ordering and temporal constraints. Like cc-Golog, it does not require the explicit specification of time.

To characterize Golog+HTN\textsuperscript{TI} we need an action theory that allows actions to have durations. For that we chose a simple extension of the language \(A\) (Gelfond & Lifschitz 1998), which we will refer to as \(AD\). We give the semantics of \(AD\) using logic programming with answer sets semantics. This (the semantics of \(AD\)) allows us to define the notion of a trajectory which we use to define the notion of a trace of a Golog+HTN\textsuperscript{TI} specification. We will begin with a short review of the answer set semantics of logic programs. We then present the language \(AD\) and discuss answer set planning with \(AD\) domains. We define the language Golog+HTN\textsuperscript{TI} and develop a logic programming based interpreter for it. Finally, we conclude with a brief discussion about future work.

Logic Programs and Answer Set Semantics
A logic program is a collection of rules of the form:

\[
a_0 \leftarrow a_1, \ldots, a_m, \text{not } a_{m+1}, \ldots, \text{not } a_n \quad \text{or} \quad (1)
\]

or

\[
a_1, \ldots, a_m, \text{not } a_{m+1}, \ldots, \text{not } a_n \quad \text{or} \quad (2)
\]

where each of the \(a_i\)’s is a literal in the sense of classical logic. \text{not } is the negation-as-failure connective. \(not \ a\) is called a naf-literal. Intuitively, the first rule means that if \(a_1, \ldots, a_m\) are true and \(a_{m+1}, \ldots, a_n\) can be safely assumed to be false then \(a_0\) must be true. The second rule is

\(^1\)Supported by NSF grants EIA-0130887, EIA-0220590. NSF grant 0070463, and NASA grant NCC2-1232.

\(^2\)The superscript \text{TI} refers to time and intervals.
a constraint that requires that at least one of \(a_1,\ldots,a_m\) is false or one of \(a_{m+1},\ldots,a_n\) is true.

The body of a rule (1) or (2) is satisfied by a set of literals \(X\) if \(\{a_1,\ldots,a_m\} \subseteq X\) and \(\{a_{m+1},\ldots,a_n\} \cap X = \emptyset\). A rule of the form (1) is satisfied by \(X\) if either its body is not satisfied by \(X\) or \(a_0 \in X\). A rule of the form (2) is satisfied by \(X\) if its body is not satisfied by \(X\).

For a set of literals \(X\) and a program \(P\), the reduct of \(P\) with respect to \(X\), denoted by \(P_X\), is the program obtained from the set of all ground instances of \(P\) by deleting \((I,\cdot)\) each rule that has a naf-literal \(\neg l\) in its body with \(l \in X\), and \((2.)\) all naf-literals in the bodies of the remaining rules. Answer sets of logic programs are first defined by Gelfond and Lifschitz in (Gelfond & Lifschitz 1990). An answer set of \(P\) if it satisfies the following conditions.

1. If \(P\) does not contain any naf-literal (i.e. \(m = n\) in every rule of \(P\)) then \(S\) is a minimal set of literals that satisfies all the rules in \(P\).
2. If the program \(P\) does contain some naf-literal \((m < n\) in some rule of \(P\)), then \(S\) is an answer set of \(P\) if \(S\) is an answer set of \(P^S\). (Note that \(P^S\) does not contain naf-literals, its answer set is defined in the first item.)

In what follows, we will refer to logic programming with answer set semantics as Answer Prolog. Answer sets of propositional programs can be computed using answer set solvers such as smodels (Simons, Niemelä, & Soininen 2002), dlv (Eiter et al. 1998), smodels (Lierler & Maratea 2003), or ASSAT (Lin & Zhao 2002). Answer set planning (ASP) (Subrahmanian & Zaniolo 1995; Lifschitz 2002) is an approach to planning using Answer Prolog, an application of answer set programming (Marek & Truszczynski 1999; Niemelä 1999) to planning. In this approach, a planning problem is translated into a logic program whose answer sets correspond one-to-one to the solutions of the original problem. To make answer set programming easier, several new types of rules have been introduced. In this paper, we will often make use of cardinality constraints of the form: \(l\{b_1,\ldots,b_k\}u \leftarrow a_1,\ldots,a_m,\neg a_{m+1},\ldots,\neg a_n\) where \(a_i\) and \(b_j\) are literals and \(l\) and \(u\) are two integers, and \(l \leq u\). Intuitively, such a rule enforces the constraint that if the body is true then at least \(l\) and at most \(u\) literals from the head are also true. Answer sets of programs with cardinality constraints are defined in (Simons, Niemelä, & Soininen 2002).

**Reasoning About Durative Actions Using LP**

As we mentioned earlier, to characterize domain constraints, we need to first describe an action description language. The action description language that we plan to use is a simple extension of the language \(A\) (Gelfond & Lifschitz 1998). In our extension, which we will refer to as \(AD\), we will allow actions to have duration and this will be sufficient to help us to justify and illustrate our language for domain constraints with new connectives.

**Syntax of \(AD\)**

An action theory consists of two finite, disjoint sets of names \(A\) and \(F\), called actions and fluents, respectively, and a set of propositions of the following form:

- \(\text{causes}(a, f)\) (3)
- \(\text{executable}(a, \{p_1,\ldots,p_n\})\) (4)
- \(\text{initially}(f)\) (5)
- \(\text{duration}(a, v)\) (6)

where \(f\) and \(p_i\)'s are fluent literals (a fluent literal is either a fluent \(g\) or its negation \(\neg g\) and \(a\) is an action. (3) is called a dynamic causal law and represents the effect of \(a\) while (4) states an executability condition of \(a\). Intuitively, a proposition of the form (3) states that \(f\) is guaranteed to be true after the execution of \(a\). An executability condition of \(a\) says that \(a\) is executable in a state in which \(p_1,\ldots,p_n\) hold. Propositions of the form (5) are used to describe the initial state. It states that \(f\) holds in the initial state. Finally, a proposition of the form (6) is used to say that duration of action \(a\) is \(v\).

An action theory is a set of propositions of the form (3)-(6). We will assume that each action \(a\) appears in one and only one proposition of the form (6) and \(v\) is a non-negative integer expression. We will often conveniently write \(d(a)\) to denote the value \(v\) if \(\text{duration}(a, v) \in D\) and for a set of actions \(A\), \(d(A) = \max\{d(a) \mid a \in A\}\).

**Example 1** Consider an action theory with the set of fluents \(\{f, g, h\}\), the set of actions \(\{a, b, c, d\}\), and the following propositions:

- \(\text{causes}(a, f)\)
- \(\text{causes}(b, h)\)
- \(\text{causes}(c, g)\)
- \(\text{causes}(d, \neg g)\)
- \(\text{initially}(\neg f)\)
- \(\text{initially}(\neg g)\)
- \(\text{initially}(\neg h)\)

The propositions about \(a\) (the first three propositions on the first line) say that \(a\) will cause the fluent \(f\) to be true after \(3\) units of time and is executable only if \(g\) and \(h\) are true. The propositions for other actions have similar meaning.

Since the characterization of \(AD\) is not the aim of this paper, we do not present an independent characterization of it. (Recall that our goal is to use \(AD\) to show how to plan using a proposed domain constraint language Golog+HTNTT.) Instead we give a AnProlog encoding of prediction and planning using \(AD\). Moreover, a transition function based semantics for \(AD\) can be defined similarly to what has been done for the language \(ADC\) in (Baral, Son, & Tuan 2002). It is worth noticing that the definitions defined herein can be easily adapted to more complex action description language such as \(ADC\).

**Semantics: Prediction in \(AD\)**

Given a set of propositions \(D\) we construct a logic program \(\pi_D\) for reasoning about the effects of actions in \(D\). The main predicates in \(\pi_D\) are:

- \(h(f, t)\) – fluent literal \(f\) holds at the time \(t\);
- \(\text{exec}(a, t)\) (resp. \(\text{in}\_\text{exec}(a, t)\)) – action \(a\) is executable (resp. in its execution) at \(t\);
- \(\text{init}(a, t)\) (resp. \(\text{ends}(a, t)\)) – action \(a\) starts (resp. ends) its execution at \(t\);

The rules of \(\pi_D\) are given next.

- For each proposition (5) in \(D\), \(\pi_D\) contains the following rule:
  \[ h(f, 1). \]  
  (7)
  This describes the initial state (which fluents hold at time point 1) as specified by propositions of the form (5) in \(D\).
- For each proposition (4) in \(D\), \(\pi_D\) contains the rules:
  \[ \text{exec}(a, T) \leftarrow \neg \text{not}\_\text{exec}(a, T). \]
  \[ \text{not}\_\text{exec}(a, T) \leftarrow \neg h(p_1, T). \]
  \[ \ldots \]
  \[ \text{not}\_\text{exec}(a, T) \leftarrow \neg h(p_n, T). \]  
  (8)
These rules define when a is executable at a time point \( T \), based only on the truth of fluents. These rules establish that a is executable if its executability condition holds.

- For each proposition (6) in \( D \), we add the following rules to \( \pi_D \).

\[
\begin{align*}
\text{ends}(a, T + v) & \leftarrow \text{init}(a, T). \\
\text{in}\_\text{exec}(a, T) & \leftarrow \text{init}(a, T'), T' < T < T + v.
\end{align*}
\]

(9)

These rules define when an action ends and when it is under execution.

- For each action a and an ef-proposition (3), the following rules are added to \( \pi_D \).

\[
\begin{align*}
h(f, T) & \leftarrow \text{ends}(a, T). \\
ab(f, T) & \leftarrow \text{in}\_\text{exec}(a, T).
\end{align*}
\]

(10)

These rules are used to reason about truth value of fluents at different time points.

**Encoding the frame axiom.** \( \pi_D \) contains the following rules that encode the frame axiom. They are slightly different from the normal logic program encoding of the frame axiom in (Gelfond & Lifschitz 1993). For each fluent \( f \), the following rules belong to \( \pi_D \):\[
\begin{align*}
h(f, T + 1) & \leftarrow h(f, T), \text{not } ab(-f, T + 1). \\
h(-f, T + 1) & \leftarrow h(-f, T), \text{not } ab(f, T + 1).
\end{align*}
\]

(11)

If we now want to find out if \( f \) would be true at time point \( t \) after starting the execution of actions \( a_1 \) at time point \( t_1 \), \( a_2 \) at time point \( t_2 \), \ldots and \( a_n \) at time point \( t_n \) all we need to do is to add the set \( \{ \text{init}(a_i, t_i) \mid i \in \{1, \ldots, n\} \} \) and the constraints \( \text{not } \text{init}(a_i, t_i) \text{not } \text{exec}(a_i, t_i) \) for \( i = 1, \ldots, n \) to \( \pi_D \), set the limits for the various variables, and ask if the resulting program entails \( h(f, t) \).

One assumption we made in our characterization is that the effect of an action takes into account only after its execution ends, and the fluents, whose value changes due to an action execution, are in an unknown state during the execution. This of course can be changed by appropriately modifying \( \pi_D \), in particular the rules in (10).

**Answer Set Planning with ADD Action Theories**

We now show how the idea of answer set planning can be extended to ADD action theories. Our AnsProlog planner for an action theory \( D \), denoted by \( \Pi(D) \), will consist of the program representing and reasoning about actions of \( D, \pi_D \), the rules representing the goal, and the rules that generate action occurrences. Besides, we will need to set the limit on the maximal number of steps (the length) of the plan. We will call it \( \text{plan}\_\text{size} \). From now on, whenever we refer to a time point \( t \), we mean that \( 1 \leq t \leq \text{plan}\_\text{size} \).

**Representing goal.** Assume that we have a goal that is a conjunction of fluent literals \( g_1 \land \ldots \land g_m \). We represent this by a set of atoms \( \{ \text{finally}(g_i) \mid i = 1, \ldots, m \} \). The following rules encode when the goal – as described by the finally facts – is satisfied at a time point \( T \).

\[
\begin{align*}
\text{not} \text{goal}(T) & \leftarrow \text{finally}(X), \text{not } h(X, T). \\
\text{goal}(T) & \leftarrow \text{not not} \text{goal}(T).
\end{align*}
\]

(12)

The following constraint eliminates otherwise possible answer sets where the goal is not satisfied at the time point \( \text{plan}\_\text{size} \).

\[
\text{not} \text{goal}(\text{plan}\_\text{size}).
\]

(13)

We now define the notion of a plan.

**Definition 1** Given an action theory \( D \), a goal \( G \), and a plan size \( \text{plan}\_\text{size} \), we say that a sequence of sets of grounded actions \( A_1, \ldots, A_n \) is a plan achieving \( G \) if \( \text{goal}(\text{plan}\_\text{size}) \) is true in every answer set of the program \( \pi_{\text{Ver}}(D, G) \), which consists of

- the rules of \( \pi_D \) and the rules representing \( G \) (rules (7)-(13)) in which the time variable is less than or equal \( \text{plan}\_\text{size} \);
- the set of action occurrences \( \bigcup^n_{i=1} \{ \text{init}(a, i) \mid a \in A_i \} \);
- the rules preventing actions with contradictory conclusions to overlap (rules (15), below).

We say that a plan \( p = A_1, \ldots, A_n \) is a concurrent plan if there exists a pair \( i \) and \( j \) and an action \( a \in A_i \cap A_j \) such that \( i + d(a) > j \), i.e., \( p \) contains an overlapping of two instantiations of a same actions. \( p \) is said to be non-concurrent if it is not a concurrent plan.

**Generating Action Occurrences.** The following rules enumerate action initiations. To decrease the number of answer sets we have made the assumption that two action instantiations corresponding to the same action can not overlap each other, i.e., we consider only non-concurrent plans. This need not be the case in general. Our point here is that AnsProlog allows us to express such restrictions very easily. For each action a with the duration \( v \), the rules:

\[
\begin{align*}
\text{act}(a, T) & \leftarrow \text{init}(a, T), T < T < T_1 + v. \\
\text{init}(a, T) & \leftarrow \text{not init}(a, T), \\
\text{exec}(a, T) & \leftarrow \text{not exec}(a, T), \text{not ninit}(a, T), \\
\text{overlap}(a, b, T) & \leftarrow \text{exec}(a, T), \text{in}\_\text{exec}(b, T), \\
\end{align*}
\]

(15)

can be used to prevent two instantiations of a to overlap. The 1st rule defines when a is active and the 3rd rule allows a to occur only if it has not been initiated and is not active. For every pair of a and b such that \( \text{causes}(a, f) \) and \( \text{causes}(b, \neg f) \) belong to \( D \), the two rules:

\[
\begin{align*}
\text{overlap}(a, b, T) & \leftarrow \text{exec}(a, T), \text{in}\_\text{exec}(b, T), \\
\end{align*}
\]

(14)

\[
\begin{align*}
\text{overlap}(a, b, T) & \leftarrow \text{exec}(a, T), \text{in}\_\text{exec}(b, T).
\end{align*}
\]

\( \text{overlap} \) can be used to disallow actions with contradictory effects to overlap. Let \( \pi_{\text{Gen}}(D, G) \) be the set of rules of \( \Pi(D) \) with the goal \( G \) and \( \text{plan}\_\text{size} \). For an answer set \( M \) of \( \pi_{\text{Gen}}(D, G) \), let \( s_1(M) = \{ f \mid h(f, i) \in M \} \) and \( A_i(M) = \{ a \mid \text{init}(a, i) \in M \} \). We can prove that there is an one-to-one correspondence between answer sets of \( \pi_{\text{Gen}}(D, G) \) and non-concurrent plans achieving \( G \).

**Theorem 1** For a theory \( D \) and a goal \( G, B_1, \ldots, B_n \) is a non-concurrent plan that achieves \( G \) iff there exists an answer set \( M \) of \( \pi_{\text{Gen}}(D, G) \) s.t. \( A_i(M) = B_i \).

**Golog+HTN:** Using Durations in Procedural and Hierarchical Domain Constraints

We begin with an informal discussion on the new construct in Golog+HTN^T1^1. Consider the domain from Example 1. It is easy to see that the program \( b; c; a \) is a program achieving \( f \) from any state and the time needed to execute this plan is the sum of the actions’s durations (Figure 1, Case (a)). Observe that \( b \) and \( c \) are two actions that achieve the condition for \( a \) to be executable and can be executed in parallel. Hence it should be obvious that any program that allows \( b \) and \( c \) to execute in parallel will have a shorter execution time. For the

\(^2\)The \( \text{Ver} \) stands for plan verification.
the construct 6 is a generalization of hierarchical task networks (HTN) (Sacerdoti 1974). The main difference is that some of them are attached to a time interval and/or a directive ‘‘‘‘/‘‘/‘‘, which are introduced for the specification of time constraints between program components. Intuitively, $φ[t_1, t_2]$ says that if it is executed at the time moment $t$ then the fluent formula $φ$ must hold during the interval $[t + t_1, t + t_2]$. The program $(p_1; c_1 | t_1, t_2) P_2$ states that $p_2$ should start its execution at least $t_1$ and at most $t_2$ units of time after $p_1$ starts whereas $(p_1; c_1 | t_1, t_2) P_2$ forces $p_2$ to wait for $t (t_1 \leq t \leq t_2)$ units of time after $p_1$ finishes. It is easy to see that $(p_1; [0, 0] P_2)$ requires that $p_1$ and $p_2$ be executed in parallel whereas $(p_1; [0, 0] P_2)$ requires that $p_2$ starts its execution at the time $p_1$ finishes. Note that $(p_1; [0, 0] P_2)$ corresponds to the original notation $p_1; p_2$.

The constraints in item 6 above are similar to truth constraints and ordering constraints over tasks in HTN. Intuitively, $p_1 \prec [t_1, t_2] p_2$ (resp. $p_1 \prec [t_1, t_2] p_2$) specifies the order and the time constraint for $p_2$ to start its execution. It states that if $p_1$ begins (resp. ends) its execution at a time moment $t$ then $p_2$ must start its execution during the interval $[t + t_1, t + t_2]$. Similarly, $(p, φ[t_1, t_2])$ (resp. $(φ[t_1, t_2], p)$) means that $φ$ must hold from $t_1$ to $t_2$ immediately after (resp. before) $p$’s execution. $(p_1, φ[t_1, t_2], p_2)$ states that $p_1$ must start before $p_2$ and $φ$ must hold $t_1$ units of time after $p_1$ starts until $t_2$ units of time before $p_2$ starts.

We note that there is a subtle difference between the constructs $\succ [t_1, t_2]$ (resp. $\prec [t_1, t_2]$) and $\succ [t_1, t_2]$ (resp. $\prec [t_1, t_2]$) in that the former (inspired by GOLOG) represents a sequential order and the latter (inspired by HTN) represents a partial order between programs. For example, during the execution of the program $(p_1; c_1 | t_1, t_2) P_2$, no other program should start its execution. On the other hand, $(p_1 \prec [t_1, t_2] p_2)$ only requires that $p_2$ should start its execution between the interval $[t_1, t_2]$ after $p_1$ starts its execution and does not prevent another program to start during the execution of $p_1$ and $p_2$.

Example 2 In our notation, $p_1$ and $p_2$ (from the discussion before Figure 1) are represented by $(b_r [0, 0]) c_r [0, 0]$ and $(b_r [0, 0] d_r | t_1, t_2) c_r [0, 0]$ respectively.

We will now define the notion of a trace of a program, which describes what actions are done when. But first we need to define the notion of a trajectory. For an action theory $D$ and an integer $n$, let $π^{Gen}(D)$ be the set of rules (7)-(11) and (14)-(15) whose time variable belongs to $\{1, \ldots, n\}$.

Definition 3 (Trajectory) For an action theory $D$ and an answer set $M$ of $π^{Gen}(D)$, let $s_1 = \{f | h(f, i) \in M\}$ and $A_i = \{a | init(a, i) \in M\}$. We say that the sequence $α = s_1 A_1 \ldots s_n A_n$ is a trajectory of $D$.

Intuitively, a trajectory is an alternating sequence of states and action occurrences $s_1 A_1, \ldots, s_n A_n$, where $s_i$ is a state at time point $i$ and $A_i$ is the set of actions that are supposed to have started at time point $i$. Observe that because of the assumption that during the execution of an action, value of fluents affected by the action is unknown, i.e., the states $s_i$ might be incomplete. However, $s_i$ will be complete if there
exists no action that is active at $i$. The notion of a trace of a program will be defined in the next four definitions.

**Definition 4 (Trace–Primitive Cases)** A trajectory $\alpha = s_1 A_1 \ldots s_n A_n$ is a trace of a program $p$ if

- $p = a, n=\emptyset(a)$ and $A_1 = \{a\}$ and $A_i = \emptyset$ for $i > 1$; or
- $p = \emptyset([t_1, t_2]), n=t_{t_2}, A_i = \emptyset$ for every $i$, and $\emptyset$ holds in $s_1$ for $t_1 \leq t \leq t_2$.

The next definition deals with programs that are constructed using GOLOG-constructs ([Levesque et al. 1997]).

**Definition 5 (Trace–Programs with GOLOG-Constructs)** A trajectory $\alpha = s_1 A_1 \ldots s_n A_n$ is a trace of a program $p$ if one of the following is satisfied.

- $p = p_1 | p_2, \alpha$ is a trace of $p_1$ or $\alpha$ is a trace of $p_2$.
- $p = \text{if } \phi \text{ then } p_1 \text{ else } p_2, \alpha$ is a trace of $p_1$ and $\emptyset$ holds in $s_1$ or $\alpha$ is a trace of $p_2$ and $\emptyset$ holds in $s_1$.
- $p = \text{while } \phi \text{ do } p_1, n = 1$ and $\emptyset$ holds in $s_1$ or $\phi$ holds in $s_1$ and there exists some $i$ such that $s_1 A_1 \ldots A_i$ is a trace of $p_1$ and $s_{i+1} A_{i+1} \ldots s_n A_n$ is a trace of $p$, or
- $p = \text{pick}(X, q(X)), \text{then } \exists x \text{ such that } \alpha$ is a trace of $q(x)$.

The trace of each program is defined based on its structure. We next deal with the new connectives $[t_1, t_2]$ and $[t_1, t_2]^\star$.

**Definition 6 (Trace–Parallel and Overlapping Programs)** A trajectory $\alpha = s_1 A_1 \ldots s_n A_n$ is a trace of a program $p$ if

- $p=p_1;[t_1, t_2]^\star p_2$, there exists two numbers $t_3$ and $t_4$ such that $t_1 + 1 \leq t_3 \leq t_2 + 1$ and $t_4 \leq n$ (because the index of the trace starts from 1) and either (i) there exists a trace $s_1 B_1 \ldots s_{t_3} B_{t_3}$ of $p_1$ and a trace $s_{t_3} B_{t_3} \ldots s_n C_n$ of $p_2$ such that $A_i = B_i \cup C_i$ for every $i$; or (ii) $t_3 \leq t_4$ and there exists a trace $s_1 B_1 \ldots s_{t_3} B_{t_3}$ of $p_1$ and a trace $s_{t_3} C_{t_3} \ldots s_{t_4} C_{t_4}$ of $p_2$ such that $A_i = B_i \cup C_i$ (we write $B_j = \emptyset$ or $C_j = \emptyset$ for indexes that do not belong to the trace of $p_1$ or $p_2$); or
- $p=p_1;[t_1, t_2]^\star p_2$, there exists two numbers $t_3$ and $t_4$ such that $t_1 + 1 \leq t_3 \leq t_2 + 1$ and $t_4 \leq n$ and $s_1 A_1 \ldots s_{t_3} A_{t_3}$ is a trace of $p_1$ and a trace $s_{t_3} A_{t_3} \ldots s_n A_n$ is a trace of $p_2$ and $A_1 = \emptyset$ for every $t_3 \leq i < t_4$.

This definition is best illustrated using a picture.

![Figure 3: $A_i = B_i \cup C_i$ – First Item, Case 1 (Definition 6)](image)

**Example 3** For $p_1=(((b_{[0,0]} c_{[0,0]} 0)) a)$ (wrt. the action theory in Example 1), we can easily check that $s_1 = \{b, c\} s_2 = \emptyset s_3 = \emptyset s_4 = \emptyset s_5 = \emptyset$ where

- $s_1 = \{-f, -g, -h\}$ $s_2 = \{-f\}$ $s_3 = \{-f, g, h\}$ $s_4 = \{g\}$ $s_5 = \{g\}$ $s_6 = \{f, g, h\}$

is a trace of $p_1$. On the other hand, we can see that $s_1 = \{b, c, d\} s_2 = \emptyset s_3 = \emptyset s_4 = \emptyset s_5 = \emptyset s_6 = \emptyset$ is not a trace of $p_1$ although it contains a trace of $p_1$.

For $p_2=(((b_{[0,0]} d_{[1,1]} c_{[0,0]} 0)) a)$ (wrt. the modified action theory), let

- $s_1 = \{-f, -g, -h\}$ $s_2 = \{-f\}$ $s_3 = \{-f, g, h\}$ $s_4 = \{g\}$ $s_5 = \{g\}$ $s_6 = \{f, g, h\}$

we can check that $s_1 = \{b, d\} s_2 = \emptyset s_3 = \{c\} s_4 = \emptyset s_5 = \emptyset s_6 = \emptyset$ is a trace of $p_2$ but it is easy to see that $s_1 = \{b, d\} s_2 = \emptyset s_3 = \{c\} s_4 = \emptyset s_5 = \emptyset s_6 = \emptyset$ is not a trace of $p_2$ because $c$ should start at the time moment 2.

We next deal with programs containing HTN-constructs.

**Definition 7 (Trace–HTN Programs)** A trajectory $\alpha = s_1 A_1 \ldots s_n A_n$ is a trace of a program $p=(S, C)$ with $S=\{p_1, \ldots, p_k\}$ if there exists two sequences of numbers $b_1, \ldots, b_k$ and $e_1, \ldots, e_k$ with $b_i \leq e_i$, a permutation $(i_1, \ldots, i_k)$ of $(1, \ldots, k)$, and a sequence of traces $a_j=s_{b_j} A_{i_j} \ldots s_{e_j} A_{i_j}$ that satisfy the following conditions:

- for each $l, 1 \leq l \leq k, \alpha_l$ is a trace of $p_{i_l}$,
- if $p_i \prec p_j \in C$ then $l_i < l_j$,
- if $p_i \prec \emptyset p_j \in C$ then $l_i < l_j$ and $b_i + q_i \leq b_j \leq b_i + q_j$,
- if $p_i \prec \emptyset p_j \in C$ then $l_i < l_j$ and $e_i + q_i \leq b_j \leq e_i + q_j$,
- if $\phi([t_1, t_2], p_i) \in C$ or $(p_i, \phi([t_1, t_2])) \in C$ then $\phi$ holds in the states $s_{b_i-t_i-2}, \ldots, s_{b_i-t_i-1}$ or $s_{e_i+t_i-1}, \ldots, s_{e_i+t_i+2}$, and
- if $(p_i, \phi([t_1, t_2], p_i)) \in C$ then $\phi$ holds in $s_{b_i-t_i-2}, \ldots, s_{b_i-t_i}$.

$A_i = \cup_{j=1}^{k} A_{i_j}$ for every $i = 1, \ldots, n$ where we assume that $A_i^j = \emptyset$ for $i < b_j$ or $i > e_j$.

The intuition of the above definition is as follows. First, each program starts ($b_i$’s) and ends ($e_i$’s) at some time point and it cannot finish before it even starts, hence, the requirement $b_i \leq e_i$. The order of the execution is specified by the ordering constraints and not by the program’s number. The permutation $(i_1, \ldots, i_k)$ and $j$’s record the starting time of the programs. The conditions on the trajectories make sure that the constraints are satisfied (first four items) and they indeed create $A_1, \ldots, A_n$ (last item).

**An AnsProlog Interpreter**

We have developed an AnsProlog interpreter for programs defined in Definitions 2. For a program $p$ of an action theory $D$, we define $\Pi(D, p)$ as a program consisting of $\Pi(D)$, the rules describing the program $p$, the set of rules for generating action occurrences (14)-(15), the constraint eliminating answer sets in which $\text{trans}(p, 1, \text{plan size})$ does not hold, and a set of rules that realizes the operational semantics of programs (Definitions 4-7). We follow the approach in [Son, Baral, & McIlraith 2001] and define a predicate $\text{trans}(p, t_1, t_2)$ which holds in an answer set $M$ of $\Pi$ iff $s_{t_1}(M) A_{t_1}(M) \ldots s_{t_2}(M) A_{t_2}(M)$ is a trace of $p^\Pi$. Space limitation does not allow a detailed presentation of $\Pi$. We therefore will concentrate on describing the ideas behind the rules and their meaning rather than presenting the rules in great detail. They can be found on our Web site.

We will begin with an informal discussion on the ideas behind the rules defining $\text{trans}(p, t_1, t_2)$. Intuitively, because of the rules (14)-(15), each answer set $M$ of the program $\Pi$ will contain a sequence of sets of actions $\alpha = A_1, \ldots, A_n$ where $A_i = \{a | \text{init}(a, i) \in M\}$. The encoding of the action theory, $\pi_D$, makes sure that whenever an action $a$ is

---

3For an answer set $M$, $s_i(M) = \{f | h(b, f, i) \in M, f$ is a fluent literal$\}$ and $A_i(M) = \{a | \text{init}(a, i) \in M\}$.

4URL: http://www.cs.nmsu.edu/~tao/ASPlan/Duration
initiated it is executable. Thus, the sequence $\alpha$ is a trajectory of $D$. So, it remains to be verified that $\alpha$ is indeed a trace of the program $p$. We will do this in two steps. First, we check if $\alpha$ contains a trace of $p$, i.e., we make sure that there is a trace $s_1B_1\ldots s_nB_n$ of $p$ such that $B_i \subseteq A_i$. Second, we make sure that no action is initiated when it is not needed and define two predicates:

- $tr(p, t_1, t_2) - s_1A_1 \ldots A_2$ contains a trace of $p$;
- $used\_in(p, q, t_1, t_2)$ - a trace of $p$ starting from $t$ is used in constructing a trace of $q$ from $t_1$ to $t_2$. Intuitively, this predicate records the actions belonging to the traces of $q$. The definition of this predicate will make sure that for a simple action $a$, only action $a$ is used to construct its trace, i.e., $used\_in(a, t_1, t_1, t_1 + d(a))$ is equivalent to $init(a, t_1)$ and $used\_in(b, a, t_1, t_1 + d(a))$ is false for every $b \neq a$.

We define that $trans(p, t_1, t_2)$ holds iff $tr(p, t_1, t_2)$ holds and for every action $a \in A_i$ for $t_1 \leq t \leq t_2$, $used\_in(a, p, j, t_1, t_2)$ holds. The rules for $tr(p, t_1, t_2)$ are similar to the rules of the predicate $trans(p, t_1, t_2)$ from (Son, Baral, & McIlraith 2001) with changes that account for action duration and the new constructs such as $[p, t_1, t_2]$ and $[p, t_1]$ and checking for the condition of new constraint on an HTN-program. The construction of $\Pi(D, p)$ allows us to prove the following theorem.

**Theorem 2** For a theory $D$ and a program $p$, (i) for every answer set $M$ of $\Pi(D, p)$, $s_1(M)A_1(M) \ldots s_n(M)A_n(M)$ is a trace of $p$, where $s_1(M) = \{ f \mid h(f, i) \in M, f$ is a fluent literal$\}$ and $A_i(M) = \{ a \mid init(a, i) \in M \}$; and (ii) if $s_1B_1s_2 \ldots s_nB_n$ is a trace of $p$ then there exists an answer set $M$ of $\Pi(D, p)$ such that $s_i = \{ f \mid h(f, i) \in M \}$ and $B_i = \{ a \mid init(a, i) \in M \}$.

**Conclusion and Discussion**

In this paper, we propose a control specification language Golog+HTN$^{TI}$ that generalizes procedural (based on GOLOG) and HTN-based specifications to allow time intervals. In the process, we generalize the connective ‘;’ to two connectives ‘$;_{[t_1,t_2]}$’ and ‘$;_{[t_1]}$’ and make similar generalizations of the HTN constructs. We then discuss the implementation of an AnsProlog-based interpreter for the language Golog+HTN$^{TI}$. Among the features that distinguish Golog+HTN$^{TI}$ from previous extensions of GOLOG are:

1. The underlying action language of Golog+HTN$^{TI}$ allows actions with duration and parallel execution.
2. The program constructs of Golog+HTN$^{TI}$ generalize the constructs of GOLOG and HTN with time and intervals.
3. It does not require an explicit specification of time.

Finally, we notice that the approach presented in this paper can be extended to allow more complex action languages that allow continuous fluents and processes such as ADC in (Baral, Son, & Tuan 2002). Besides its use as a specification language similar to cc-Golog, Golog+HTN$^{TI}$ can also be viewed as a language for specifying domain-dependent knowledge in a planner, a view explored by (Son, Baral, & McIlraith 2001) with respect to GOLOG. There, they demonstrated that a simplified version of programs discussed in this paper can help improving the performance of planner. To investigate this use of Golog+HTN$^{TI}$, we have developed a prototype of a planner for domains with continuous fluents and durative actions that uses Golog+HTN$^{TI}$ with encouraging results. We will report our experiments with Golog+HTN$^{TI}$ in planning in a future work.
