Overview of Current Projects

There is currently considerable interest in using middleware technology to integrate sources of data and knowledge. Some of these sources are legacy systems (pre-existing databases and expert systems), while others are custom-built services specifically designed to operate as components within distributed information architectures. Some of the common scenarios served by such architectures are:

- extracting data from databases and providing it as the input to knowledge-based systems, which in turn derive new information;
- extracting data from databases and knowledge from knowledge bases, and combining both to compose a new information source;
- extracting and transforming data and knowledge into constraint programs, the solution of which yields new information.

Some example instantiations of these scenarios in actual application domains are:

- distributed engineering design, where data on components is combined with knowledge of how designs are composed, and constraints given by the customer's requirements (for example, configuring a modular computer system);
- medical informatics systems, where patient data is fed into expert systems for therapy recommendation or critiquing (for example, recommending appropriate drugs based on the patient's needs and current drug usage);
- University admissions systems, where appropriate programmes of study can be offered, based on the student's needs and consistent with data on their academic history (for example, knowledge of prerequisites can be checked against the student's database entry from their previous institution).

At Aberdeen, we have a number of current projects developing technology to support such scenarios. We favour an agent-based architecture for these projects, in which there are three types of agent, but any agent is potentially able to communicate with any other:

User Agents These are components that interact directly with human users; typically they offer graphical user interfaces; sometimes they are embedded in Web pages in the form of Java applets.

Resource Agents These are resources — databases or knowledge-based systems — which have been "agentified" by providing them with an agent front-end.

Middleware Agents These are the agents that actually provide the database and knowledge base integration services; typically, each performs some useful task, on request from some other agent or on its own "initiative", and calling upon the services of other agents.

Our agents communicate using an agent communication language (generally a variant of KQML), implemented on top of a distributed object messaging mechanism (currently either CORBA IOP or Java RMI). Various directory services allow agents to discover one another dynamically at run-time; these range from the simple directory services offered by CORBA and Java RMI, to richer agent-oriented advertisement and brokerage services.

A selection of our current projects are briefly described below.

KRAFT: Knowledge Reuse and Fusion/Transformation KRAFT is a three year, multiple-site research project involving the Universities of Aberdeen, Cardiff and Liverpool, and British Telecom. Funded by the EPSRC and BT, KRAFT aims to create a generic architecture for sharing knowledge in the form of constraints. Constraint knowledge is extracted on demand from databases and knowledge-bases, transformed to a shared ontology, and delivered to an appropriate solver. Middleware agents include mediators, which locate and transform the constraints, and facilitators, which provide sophisticated directory and brokerage services. KRAFT is specifically intended to support distributed engineering design applications, and a prototype application is currently under construction. An overview of the project has been published in (Gray et al. 1997).
