Abstract
We propose a simple model of interaction for resource-conscious agents. The resources involved are expressed in fragments of Linear Logic. We investigate a few problems relevant to cooperative games, such as deciding whether a group of agents can form a coalition and act together in a way that satisfies all of them. In terms of solution concepts, we study the computational aspects of the core of a game. The main contributions are a formal link with the existing literature, and complexity results for several classes of models.

Introduction
One crucial theme in multi-agent systems is the one of resource-conscious agents. As the research in multi-agent systems is advancing and one can predict its future widespread implementation in real-world systems, one needs to acknowledge that the agents evolving in the real world have limited access to resources. They have to seek after resource objectives and compete for those resources. When unable to attain a resource alone, they might have to form coalitions.

In their abstract definition, coalitional games are presented as a tuple $(\mathcal{Ag}, \text{VAL})$, where $\mathcal{Ag}$ is a set of agents, and $\text{VAL} : 2^{\mathcal{Ag}} \rightarrow \mathbb{R}$ is a coalition collective value. Typically, we assume that $\text{VAL}(\emptyset) = 0$. We call simple game a coalitional game such that for every coalition $C \subseteq \mathcal{N}$, we have $\text{VAL}(C) = 0$ or $\text{VAL}(C) = 1$. Where these utilities come from however is not part of the description. Here, each player $i$ of a game is endowed with a multiset of resources $\mathcal{en}_i$. An action for Player $i$ consists in contributing a subset of $\mathcal{en}_i$. Then, each player $i$ has a set of goals $G_i$, which is a set of resources, represented by formulas of some resource-sensitive logic LOG. In the resulting coalition games, the valuation function will depend of these individual endowments and goals.

Example 1. Consider the following setting that will be fully formalised later. Player 1 is happy with bacon, Player 2 is happy with either bacon or an egg, and Player 3 is happy with an omelet. Player 1 is endowed with one egg and the capacity of using an egg to make an omelet. Player 2 is endowed with bacon. Player 3 is endowed with one egg.

Player 2 is self-reliant as she can eat her bacon and be happy. To make Player 1 happy as well, this bacon must be used towards the happiness of Player 1. In this case, it is Player 1’s egg that will be used towards Player 2’s happiness. To add Player 3 into the happy team, Player 3 can provide his egg, which can be transformed into an omelet using Player 1’s still uncommitted capacity of transforming and egg into an omelet. The value of the coalitions $\{2\}$, $\{1, 2\}$, and $\{1, 2, 3\}$ is thus 1.

In this paper, we propose simple models of interaction capable of representing and reasoning about scenarios such as Example 1, where resources can be intricately consumed, transformed, and produced by agents. They are compact coalitional games reminiscent of (Wooldridge and Dunne 2006) and (Bachrach and Rosenschein 2008). We propose what is effectively an extension of coalitional resource games (Wooldridge and Dunne 2006) that takes advantage of resource-sensitive logics. The exact resource-sensitive logic will be a parameter LOG, which can be instantiated with any variant and fragment of Linear Logic (Girard 1987), Bunched Logic (O’Hearn and Pym 1999), etc.

We briefly present the Linear Logic formalism in the next section. The results of this paper will be applicable to every fragment and variant of Linear Logic mentioned there.

In Linear Logic, a formula can be interpreted as a resource. It has been used before in social choice and game theory, e.g., (Porello and Endriss 2010a; 2010b; DeYoung and Schürmann 2012; Troquard 2016). The propositional language of Linear Logic can distinguish simultaneous availability of resources ($A \otimes B$), deterministic ($A & B$) and non-deterministic ($A \oplus B$) choices between resources, resource transformations ($A \multimap B$), and anti-resources ($\sim A$). For instance, $\$1 \multimap (\$1 \otimes \$1) \oplus 1$ captures a capacity of gambling, where if an agent gives $\$1$, they receive $\$2$ or nothing (the vacuous resource $1$), and do not get to choose. On the other hand, $\$10 \multimap \text{fish} & \text{meat}$ captures a capacity of buying a meal, where if an agent gives $\$10$, they receive a meal of fish or a meal of meat, and they choose which one. Moreover, the resource-consciousness is a built-in feature of the entailment of these logics. For instance, it is not the case that $\$1 \vdash \$1 \otimes \$1$, unlike its classical counterpart $\$1 \vdash \$1 \land \$1$.

Having resources and goals represented in the same way has important consequences. The language of Linear Logic
allows us to represent at the same level of abstraction, simultaneous resources, two kinds of disjunctions, and crucially, resource-transforming capacities (e.g., transforming one egg into an omelet). This becomes all the more significant when the resources are subject to a series of transforming activities. In contrast, in the coalitional resource games from (Wooldridge and Dunne 2006), resources become goals, and ’game over’.

Furthermore, using Linear Logic, we can exploit the existing research in logic proofs and automated proofs. Through the Curry-Howard correspondence between proofs and programs (see, e.g., (Gabbay and de Queiroz 1992)), an exciting perspective is the possibility to interpret the logical proofs as rigorous programs to be executed by the coalitions. Hence, one goal of this research is the automated generation of cooperative plans, where the resources can be subjected to a series of transforming activities by the agents.

We first provide a brief summary of the formal aspects of Linear Logic that we use in this paper. We present the coalitional resource games (CRG) from (Wooldridge and Dunne 2006) and we introduce the class of rich coalitional resource games (RCRG). We then propose a translation of CRGs into RCRGs that preserves the set of goals that are feasible for the coalitions. Next, we study a few decision problems: deciding whether a coalition is winning, deciding whether a player is a veto player, deciding whether a player is a dummy player, and deciding whether the core of a game is non-empty. A formalization of Example 1 is then presented before the conclusion.

Linear Logic

A good introduction to Linear Logic and its variants is (Troelstra 1992).

MLL is the multiplicative fragment of Linear Logic: \( A ::= 1 \mid [p] \sim A \mid A \otimes A \mid A \to A \), where \( p \) is an atomic formula. MALL is the fragment with both additive and multiplicative operators: \( A ::= \top \mid 0 \mid [p] \sim A \mid A \otimes A \mid A \to A \mid A \& A \mid A + A \). We say that the logic is affine when it admits the structural rule of weakening (\( \overline{\top} \)).

We only present the sequent rules for affine MALL that are used in this paper. See (Troelstra 1992) for the complete sequent calculus. \( A \), \( B \) are formulas. \( \Gamma, \Gamma', \Delta, \) and \( \Delta' \) are sequences of zero or more formulas.

\[
\begin{align*}
A &\vdash A, &\text{x} &\text{1R}\quad \Gamma, \Delta \vdash A, B, \Delta' &\vdash E\quad \Gamma, \Delta \vdash A, B, \Delta' &\vdash W
\end{align*}
\]

\[
\begin{align*}
\Gamma, \Delta &\vdash \Gamma, \Delta, &\text{R}\quad \Gamma, \Gamma, \Delta, \Delta' &\vdash &\Gamma, \Delta &\vdash A, B, \Delta', &\vdash &\Delta &\vdash A, B, \Delta', \Delta
\end{align*}
\]

Affine MLL is obtained by removing the rules involving \&, +, \top and 0. MALL is the logic obtained by removing the rules (\( \overline{W} \)) (of which only one is used here). MLL is obtained by removing the rules (\( \overline{W} \)) and the rules involving \&, +, \top and 0 (of which only one is used here).

We quickly summarize the complexity of some fragments and variants of Linear Logic. MALL is PSPACE-complete; MLL is NP-complete; Affine MLL is NP-complete; Affine MALL is PSPACE-complete; Intuitionistic MALL is PSPACE-complete; Intuitionisitc MALL is NP-complete. First-Order MLL is NP-complete and First-Order MALL is NEXPTIME-complete. Something particularly interesting is that these fragments of Linear Logic behave well computationally also in the first-order case. It is in contrast with First-Order classical logic which is undecidable. First-Order MLL is NP-complete and First-Order MALL is NEXPTIME-complete. See (Lincoln et al. 1992; Kanovich 1994).

Coalitional Games

We first present the coalitional resource games from (Wooldridge and Dunne 2006). Then we introduce a variant that makes use of Linear Logic to represent rich resources.

Coalitional Resource Games

Coalitional resource games were introduced in (Wooldridge and Dunne 2006).

**Definition 2.** A coalitional resource game (CRG) is a tuple \( \Gamma = (A_i, G, (G_i)_{i \in Ag}, R, en, req) \) where:

- \( Ag = \{ a_1, \ldots, a_n \} \) is a set of agents;
- \( G = \{ g_1, \ldots, g_m \} \) is a set of possible goals;
- \( R = \{ r_1, \ldots, r_t \} \) is a set of resources;
- for each agent \( i \in Ag \), the set \( G_i \subseteq G \) collects the goals agent \( i \) would be satisfied with;
- \( en : Ag \times R \rightarrow \mathbb{N} \) is an endowment function;
- \( req : G \times R \rightarrow \mathbb{N} \) is a requirement function.

In addition, we assume \( \forall g \in G, \exists r \in R : req(g, r) > 0 \).

Endowment and requirement functions are naturally extended. We define: \( en(C, r) = \sum_{i \in C} en(i, r) \) and \( req(H, r) = \sum_{g \in H} req(g, r) \). We say that a set of goals \( H \) satisfies agent \( i \) if \( H \cap G_i \neq \emptyset \); it satisfies a coalition \( C \) if it satisfies all its members. We define the set of sets of goals that satisfy coalition \( C \) as \( sat(C) = \{ H \subseteq G \mid \forall i \in \{ i \in C, H \cap G_i \neq \emptyset \} \} \). We say that a set of goals \( H \) is feasible for a coalition when the coalition is endowed with enough resources to achieve all the goals in \( H \). We define the set of feasible sets of goals of coalition \( C \) as \( feas(C) = \{ H \subseteq G \mid \forall r \in R, req(H, r) \leq en(C, r) \} \). Finally, we denote the set of sets of goals that are feasible by coalition \( C \) and satisfy coalition \( C \) with \( sf(C) = sat(C) \cap feas(C) \).

Rich Coalitional Resource Games

We propose a variant of coalitional resource games that makes use of resource-sensitive logics. The exact resource-sensitive logic is a parameter LOG, which can be instantiated with any variant and fragment of Linear Logic (Girard 1987). We assume that the language of LOG is at least the one of MLL.

In RCRGs, resources and goals are the same type of objects: LOG formulas. Resources can then be combined and transformed following the rules of LOG so as to yield goals. As the translation from CRGs to RCRGs will make clear in the next section, the requirement function of CRGs can be built in the very formulas that represent endowed resources.
Definition 3. A rich coalitional resource game (RCRG) is a tuple $\Gamma = (A, G, (G_i)_{i \in A}, e_n)$ where:

- $A = \{a_1, \ldots, a_n\}$ is a finite set of agents;
- for each agent $i \in A$, the finite non-empty set $G_i \subseteq \text{LOG}$ collects the goals agent $i$ would be satisfied with;
- $G$ is a finite multiset of possible goals. We assume $\bigcup_{i \in A} G_i \subseteq G$;
- for every $i \in A$, the finite multiset $e_n_i$ $\subseteq \text{LOG}$ is agent $i$'s endowment.

Endowments are naturally extended to coalitions. We define: $e_n_C = \bigcup_{i \in C} e_n_i$. We say that a multiset of goals $H \subseteq G$ satisfies coalition $C \subseteq A$ if there is $(g_1, \ldots, g_n) \in \prod_{i \in A} G_i$ such that $\bigcup_{i \in C} \{g_i\} \subseteq H$. We define the set of multisets of goals that satisfy coalition $C$ as $\text{sat}_C(C) = \{H \subseteq G | \text{H satisfies C}\}$. We say that a multiset of goals $H \subseteq G$ is feasible for a coalition $C$ when there is $E \subseteq e_n_C$ such that $E \vdash \bigotimes H$. We define the set of multisets of goals for which the coalition $C$ is feasible as follows: $\text{feas}_C(C) = \{H \subseteq G | \text{H is feasible for C}\}$. The set of multisets of goals that are feasible by coalition $C$ and satisfy coalition $C$ is defined as before with $s_f(C) = \text{sat}_C(C) \cap \text{feas}_C(C)$.

Restricted classes of RCRG. We will successively focus our attention on some variants of RCRG. There will be three varying dimensions. (i) Affine RCRGs add to the deductive power of the underlying logic LOG. (ii) MLL and MALL RCRGs modify the expressivity of the underlying logic LOG. (iii) One-goal RCRGs adds constraints on the number of goals of each player.

Weakening, rule (W), is a structural rule that accounts for the monotonicity of the entailment of a logic. Linear Logic does not admit the weakening rule, but affine logic does. However, it has generally no effect on the complexity of the problem of sequent validity. Sequent validity in MLL is NP-complete with or without weakening and sequent validity in MALL is PSPACE-complete with or without weakening. On the other hand, whether LOG admits weakening or not will have dramatic consequences for the algorithmic solutions to the decision problems in RCRG.

Definition 4. An affine RCRG is an RCRG instantiated with LOG admitting weakening (rule (W)).

The exact syntactic variant chosen for LOG will of course have an effect on the complexity results.

Definition 5. A MLL RCRG is an RCRG instantiated with LOG being MLL. A MALL RCRG is an RCRG instantiated with LOG being MALL.

Finally, we propose a variant that imposes a restriction on the number of goals for each player.

Definition 6. A one-goal RCRG is an RCRG $\Gamma = (A, G, (G_i)_{i \in A}, e_n)$ where $|G_i| = 1$.

Remark 7. One-goal RCRGs, and MALL RCRGs in particular, are often “enough”. In CRGs, multi-goals are essentially disjunctive goals: a player is happy when one of her goals is satisfied. With the Linear Logic language of resources, we can satisfyingly capture disjunctive goals in one-goal RCRGs. We can even decide which kind of non-deterministic goal to use! We can use the connective $\oplus$ e.g., egg $\oplus$ bacon, to indicate that the player wants either egg or bacon. (We will use this goal in the formalisation of Example 1 later.) We can use the connective $\&$, e.g., egg$\&$bacon to emphasize that the player wants to retain the choice between egg and bacon.

From CRGs to MLL RCRGs

Let $\Gamma = (A, G, R, (G_i)_{i \in A}, e_n, \text{req})$ be a CRG. For every goal $g \in G$, we reserve an atomic proposition $p_g$ in LOG. For every resource $r \in R$, we reserve an atomic proposition $p_r$ in LOG. For every goal $g \in G$, we write $p_g = \bigotimes_{r \in R} (p_r \oplus \cdots \oplus p_r)_{\text{req}(g,r) \text{ times}}$.

It is a formula of LOG that characterises the requirement in terms of resources of the goal $g$. We build the RCRG $\Gamma^R = (A^R, G^R, (G^R_i)_{i \in A^n}, e_n^R)$ as follows:

- $A^R = A$;
- $G^R = \bigcup_{g \in G}\{p_1, \ldots, p_g\}$;
- $G^R_i = \{p_g | g \in G_i\}$;
- $e_n^R = \bigcup_{r \in R}(p_{r_1} \oplus \cdots \oplus p_{r_\text{req}(g,r) \text{ times}})$

Observe that we do not use any additive operator. It is enough to define the constructed $\Gamma^R$ to be an MLL RCRG.

Remark 8. This translation from CRGs to RCRGs is meant as a rigorous and formal comparison of RCRGs with the existing literature. This translation, however, is not meant to suggest that CRGs problems should be solved within the framework of RCRGs. Indeed, the proposed translation from CRGs to RCRGs obviously causes a blowup when the numbers in the CRG are encoded in binary. Interestingly, in (Wooldridge and Dunne 2006), the complexity results for CRGs are “strong”: the problems stay in the same class when one uses very inefficient number representations.

The next example illustrates the construction.

Example 9. Let $\Gamma_1$ be the CRG defined in (Wooldridge and Dunne 2006, Example 1) where $A = \{a_1, a_2, a_3\}$, $G = \{g_1, g_2\}$, $R = \{r_1, r_2\}$, the goals are given by $G_{a_1} = \{g_1\}$ $G_{a_2} = \{g_2\}$ $G_{a_3} = \{g_1, g_2\}$, the endowment function is $en(a_1, r_1) = 2$ $en(a_1, r_2) = 0$ $en(a_2, r_1) = 0$ $en(a_2, r_2) = 1$ $en(a_3, r_1) = 1$ $en(a_3, r_2) = 2$,
and the requirement function is
\[ \text{reg}(g_1, r_1) = 3 \quad \text{reg}(g_1, r_2) = 2 \quad \text{reg}(g_2, r_1) = 2 \quad \text{reg}(g_2, r_2) = 1. \]

The RCRG \( \Gamma^R \) is thus defined with \( A^R = \{a_1, a_2, a_3\} \), \( G^R = \{p_1, p_2, p_3, p_4, p_5, p_6, p_7, p_8\} \) with individual goals \( G^R_{a_1} = \{p_1, p_2\} \), \( G^R_{a_2} = \{p_3, p_4, p_5\} \), and \( G^R_{a_3} = \{p_6, p_7, p_8\} \), and the endowment function is:
\[ e_{a_1}^R = \{p_{r_1}, p_{r_1}\} \cup \{p_{r_1} \otimes p_{r_2}, p_{r_2} \otimes p_{r_2}, p_{r_3} \otimes p_{r_2}, p_{r_2} \otimes p_{r_3} \}, \]

where \( p_{r_1} = p_{r_1} \otimes p_{r_1} \otimes p_{r_1} \otimes p_{r_2} \otimes p_{r_2} \otimes p_{r_2} \otimes p_{r_3} \otimes p_{r_3} \).

In (Wooldridge and Dunne 2006), the authors study the relationship between CRG and Qualitative Coalitional Games (QCG) from (Wooldridge and Dunne 2004). A CRG and a QCG are said to be equivalent if the agents and the goals correspond, and there is a correspondence between the feasible sets of goals. We use the point of comparison here. We show that for every CRG \( \Gamma \), there is a correspondence between the feasible sets of goals in \( \Gamma \) and in the RCRG \( \Gamma^R \) obtained by the previous construction.

**Proposition 10.** Let \( \Gamma = (A_G, G, R, (G_i)_{i \in A_G}, e_n, \text{reg}) \) be a CRG. For every coalition \( C \subseteq A_G \) and every set of goals \( H \subseteq G \), we have
\[ H \in \text{feast}_R(C) \iff \bigcup_{g \in H} \{p_g\} \in \text{feast}_{\Gamma^R}(C). \]

Proof: (sketch) We omit the proof of the right to left direction. From left to right. We build the RCRG \( \Gamma^R = (A_G^R, G^R, (G_i^R)_{i \in A_G^R}, e_{n}^R) \). Let \( C = \{c_1, \ldots, c_r\} \). Suppose \( H \in \text{feast}_R(C) \). It means that \( \forall r \in R, \text{reg}(H, r) \leq e_n(C, r) \). To achieve \( H \), the contribution of agent \( i \in C \) in terms of the resource \( r \in R \) is the natural number \( \kappa_H(i, r) \leq e_n(i, r) \).

Winning coalitions

Let \( \Gamma \) be an RCRG, and \( \Gamma \) a non-empty coalition. We say \( C \) is winning when \( \text{val}_\Gamma(C) \neq 0 \), and that is losing otherwise. We assume that the empty coalition is losing. When \( C \) is winning in \( \Gamma \), we also say that the value of coalition \( C \) is 1, written \( \text{val}_\Gamma(C) = 1 \). When \( C \) is losing, we say that the value of coalition \( C \) is 0, written \( \text{val}_\Gamma(C) = 0 \). An RCRG \( \Gamma \) associated with the valuation function \( \text{val}_\Gamma \) is thus effectively a simple game.

**Example 11.** In the CRG \( \Gamma_1 \) defined in Example 9, we have \( \{a_2\} \in \text{feast}_{\Gamma_1}(\{a_1, a_2\}) \). By Prop. 10, it must be that in the RCRG \( \Gamma^R_1 \), we have \( \{p_{a_2}\} \in \text{feast}_{\Gamma^R_1}(\{a_1, a_2\}) \). We show that it is indeed the case. Let \( E_{a_1} = \{p_{r_1}, p_{r_1}\} \subseteq e_{n}^R \) and \( E_{a_2} = \{p_{r_2}, p_{r_2} \otimes p_{r_2}, p_{r_2} \otimes p_{r_2}, p_{r_2} \otimes p_{r_2} \} \subseteq e_{n}^R \). We can formally demonstrate that \( E_{a_1}, E_{a_2} \vdash p_{a_2} \).

It is indeed a simple example, and it admits simple proofs involving only the rules (ax) and (\$R\$). We see that \( \text{val}_\Gamma(\{2, 3\}) = 1 \). So \( \{2, 3\} \) is a winning coalition. To see it, take \( E_2 = e_n = \{A\} \), and \( E_3 = e_n = \{A\} \). We can prove that \( E_2, E_3 \vdash (A \otimes A) \otimes A \), as follows:

\[ A \vdash A \quad A \vdash A \quad A \vdash A \quad A \vdash A \]

**Remark 13.** RCRGs are in general neither monotonic nor superadditive. The former may be unusual, while the latter is particularly expected for a class of simple games. In general, RCRGs are not monotonic. In Example 12 we can see that \( \text{val}_\Gamma(\{1\}) = 1 \), but \( \text{val}_\Gamma(\{1, 2\}) = 0 \). In general, RCRGs are not superadditive. In Example 12 we can see that \( \text{val}_\Gamma(\{1\}) = 1 \) and \( \text{val}_\Gamma(\{3\}) = 1 \), but \( \text{val}_\Gamma(\{1, 3\}) = 1 < \text{val}_\Gamma(\{1\}) + \text{val}_\Gamma(\{3\}) \).

The problem WIN is defined as follows.

**Definition 14.** Let \( \Gamma \) be an RCRG. WIN: Given a coalition \( C \subseteq A_G \), answer the question “\( \text{val}_\Gamma(C) = 1? \)”.

1245
In (Wooldridge and Dunne 2004), it is shown that \textsc{WIN} (called \textsc{SUCCESSFUL COALITION} there) is NP-complete for CRGs. In this section, we prove the results summarized in Table 1.

The correctness of Algorithm 1 for \textsc{WIN} is immediate from the definitions. The complexity follows from a simple analysis and the fact that the line 2 can be evaluated in polynomial space when LOG is MALL and in non-deterministic polynomial time when LOG is MLL (Lincoln et al. 1992). Since \text{NP} = \Sigma_2^P \land \text{NP} = \text{PSPACE}, we obtain:

**Proposition 15.** \textsc{WIN} is in \Sigma_2^P for MLL CRGs, and in PSPACE for MALL CRGs.

Finally, we consider the case of affine CRGs, for which we are able to provide tight complexity results for the \textsc{WIN} problem. There is a polynomial-time many-one reduction from instances of the problem of sequent validity for affine LOG, into instances of the problem of \textsc{WIN} for affine CRG.

**Proposition 16.** \textsc{WIN} for affine CRGs is as hard as sequent validity in the underlying logic LOG.

**Proof.** By applying the rules (\textsc{~L}) and (\textsc{R}), \(A_1, \ldots, A_n \vdash B_1, \ldots, B_m\) iff \(A_1, \ldots, A_n, \sim B_2, \ldots, \sim B_m \vdash B_1\) is immediate. Thus, w.l.o.g., we can restrict our attention to intuitionistic sequents, of the form \(A_1, \ldots, A_n \vdash B\). From such a sequent, we construct the (affine) non-deterministic CRG \(\Gamma = (A_g, G, \{G_i\}_{i \in Ag}, en)\) as follows. \(A_g = \{a\}; G = \{B\}\); \(G_a = \{B\}\); \(\text{en}_a = \{A_1, \ldots, A_n\}\). We want to show that \(A_1, \ldots, A_n \vdash B\) if and only if \(s_f(\{a\}) \neq \emptyset\).

From left to right. Let \(H = \{B\} \subseteq G\). Clearly \(B \in G_a\) and \(\{B\} \subseteq H\). So, \(H \in \text{sat}_f(\{a\})\). Now, suppose \(A_1, \ldots, A_n \vdash B\). Since \(A_1, \ldots, A_n \subseteq \text{en}_a\), we clearly have that \(H \in \text{feas}_f(\{a\})\). So \(H \in \text{sat}_f(\{a\}) \cap \text{feas}_f(\{a\}) \neq \emptyset\).

From right to left. Suppose \(s_f(\{a\}) \neq \emptyset\). It means that \(\exists H \in \text{sat}_f(\{a\}) \cap \text{feas}_f(\{a\})\). By definition of \(\text{feas}_f\), necessarily \(H = \{B\}\). By definition of \(\text{sat}_f\) and \(\text{en}_a\), \(E_a \subseteq \{A_1, \ldots, A_n\}\).

For one-goal affine CRGs, we can reduce the problem of \textsc{WIN} for one-goal affine CRGs to the problem of sequent validity in the affine LOG. This is stated by the following lemma.

**Lemma 17.** Let \(\Gamma = (A_g, G, \{g_i\}_{i \in Ag}, en)\) be a one-goal affine CRG, and let \(C \subseteq Ag\) be a coalition. \(s_f(C) \neq \emptyset\) iff \(\text{en}_C \vdash \bigotimes_{i \in C} g_i\).

**Proof.** Right to left is immediate. For left to right, suppose \(s_f(C) \neq \emptyset\). Since the CRG is one-goal, there is only one \textsc{WIN} problem. There is a polynomial-time many-one reduction from the definitions. The complexity follows from a simple reduction.

From Lemma 17 and Proposition 16, we obtain the following result.

**Proposition 18.** \textsc{WIN} is NP-complete for one-goal affine MLL CRGs and PSPACE-complete for one-goal affine MALL CRGs.

The problem \textsc{WIN} is central, and instrumental for other problems, some of which we study the next section.

**The core of one-goal affine CRGs**

When studying the powers of coalitions, there are at least two remarkable types of players: dummy and veto. CRG are simple games, and in simple games, Player \(i\) is a veto player when there is no winning coalition without Player \(i\)'s contribution. Let \(\Gamma = (A_g, G, \{G_i\}_{i \in Ag}, en)\) be an CRG. Player \(i\) is a veto player if for every coalition \(C \subseteq Ag\), if \(C\) is a winning coalition, then \(i \in C\). On the other hand, Player \(i\) is a dummy player when its presence or absence in a coalition does not change the value; it has neither a positive nor a negative impact. Player \(i\) is a dummy player if for every coalition \(C \subseteq Ag\) we have \(\text{VAL}_f(\emptyset \cup \{i\}) = \text{VAL}_f(C)\).

A payoff vector specifies how the gains of the grand coalition are distributed among the players. A payoff vector is a tuple \(p = (p_1, \ldots, p_n) \in \mathbb{R}^n\) such that \(\sum_{i \in Ag} p_i = \text{VAL}_f(\emptyset)\). The value \(p_i\) denotes the payoff of agent \(i\). The payoff of coalition \(C \subseteq Ag\) is defined as \(p_C = \sum_{i \in C} p_i\). If the value of a coalition is strictly greater than its payoff from \(p\), its members have an incentive to break from the grand coalition and work together to achieve its actual value; we say the coalition blocks \(p\). The coalition \(C\) blocks the payoff vector \(p\) if \(p_C < \text{VAL}_f(C)\). The core of a game is an important solution concept.

**Definition 19.** Let \(\Gamma = (A_g, G, \{G_i\}_{i \in Ag}, en)\) be an CRG. The core is the set of payoff vectors that are not blocked by any coalition.

In this section, we study the following problems.

**Definition 20.** Let \(\Gamma = (A_g, G, \{G_i\}_{i \in Ag}, en)\) be an CRG.

**\textsc{VETO}:** Given a player \(i \in Ag\), answer the question “is \(i\) a veto player?”. \textsc{DUMMY}: Given a player \(i \in Ag\), answer the question “is \(i\) a dummy player?”. \textsc{CNE}: Answer the question “is the core non-empty?”.

From now on, we shall concentrate on one-goal affine CRGs. We prove the results summarized in Table 2 and Table 3.

**\textsc{VETO}**

Given an CRG \(\Gamma\), and a player \(i\), deciding \textsc{VETO} is done by checking that Player \(i\) is a member of all winning coalitions: \(\forall C \subseteq Ag\), if \(\text{VAL}_f(C) = 1\) then \(i \in C\).
Class of RCRG & WIN \\
MLL & in $\Sigma^p_2$ (Prop. 15) \\
MALL & in PSPACE (Prop. 15) \\
Affine MALL & PSPACE-complete (Prop. 15, Prop. 16) \\
One-goal affine MLL & NP-complete (Prop. 18) \\
One-goal affine MALL & PSPACE-complete (Prop. 18) \\

Table 2: Complexity upper-bounds of VETO, DUMMY, and CNE in one-goal affine RCRGs

Algorithm 2 Non deterministic algorithm for coVETO

IN: an RCRG $\Gamma = (Ag, G, (G_i)_{i \in Ag}, en)$, a player $i \in Ag$
OUT: true if $i$ is not a veto player in $\Gamma$, false otherwise
1: non-deterministically guess $C \subseteq Ag \setminus \{i\}$.
2: return “$C$ is winning?”.

The complexity membership of VETO follows from a simple analysis of Algorithm 2, together with Proposition 18.

Proposition 21. In one-goal RCRGs, VETO is in $\Pi^p_2$ when LOG is affine MLL, and in PSPACE when LOG is affine MALL.

We show that deciding VETO for a class $C$ of RCRG is as hard as deciding coWIN in one-goal $C$.

Proposition 22. In one-goal RCRGs, VETO is coWIN-hard.

Proof. (sketch) Let $\Gamma = (Ag, G, (G_i)_{i \in Ag}, en)$ be a one-goal RCRG and let $C \subseteq Ag$ be a coalition. We build the 2-player one-goal RCRG $\Gamma' = (\{a, b\}, \{g_a, g_b\}, \{en_a, en_b\})$ where $g_a = 1$, $en_a = \emptyset$, $g_b = \bigotimes_{i \in C} g_i$, $en_b = en_C$. We can show that $C'$ is winning in $\Gamma'$ iff Player $a$ is not a veto player in $\Gamma'$.

DUMMY

Algorithm 3 Non deterministic algorithm for coDUMMY

IN: an RCRG $\Gamma = (Ag, G, (G_i)_{i \in Ag}, en)$, a player $i \in Ag$
OUT: true if $i$ is not a veto player, false otherwise
1: non-deterministically guess $C \subseteq Ag$.
2: $win_C := \text{“}C \text{ is winning}\text{”}$
3: $win_{C \setminus \{i\}} := \text{“}C \setminus \{i\} \text{ is winning}\text{”}$
4: return “(win$_C$ and not win$_{C \setminus \{i\}}$) or (not win$_C$ and win$_{C \setminus \{i\}}$)”.

We can employ Algorithm 3. Together with Proposition 18, its analysis yields the following result.

Proposition 23. In one-goal RCRGs, DUMMY is in $\Pi^p_2$ when LOG is affine MLL, and in PSPACE when LOG is affine MALL.

We show that deciding DUMMY for a class $C$ of RCRG is as hard as deciding coWIN in one-goal $C$.

Proposition 24. In one-goal RCRGs, DUMMY is coWIN-hard.

Proof. (sketch) Let $\Gamma = (Ag, G, (G_i)_{i \in Ag}, en)$ be a one-goal RCRG and let $C \subseteq Ag$ be a coalition. We build the 1-player one-goal RCRG $\Gamma' = (\{a\}, \{g_a\}, (en_a))$ where $g_a = \bigotimes_{i \in C} g_i$, and $en_a = en_C$. We can show that $C$ is winning in $\Gamma'$ iff Player $a$ is not a dummy player in $\Gamma'$.

CNE

We characterise the existence of an imputation in the core through three lemmas. When the grand coalition $Ag$ is winning, CNE depends on the existence of a veto player.

Lemma 25. If the grand coalition is winning, then the core of an RCRG is non-empty iff there is a veto player.

Proof. (sketch) Assume $\text{VAL}_T(Ag) = 1$. We only show the left to right direction. Let $p = (p_1, \ldots, p_n)$ be a payoff vector in the core. By definition, it is not blocked by any coalition: for all $C \subseteq Ag$, we have $p_C = \sum_{i \in C} p_i \geq \text{VAL}_T(C)$. Now pick $v \in Ag$, such that $p_v > 0$ (such a player exists because $Ag$ is winning and $p_{Ag} = \text{VAL}_T(Ag) = 1$). We show that $v$ is a veto player. Let $C$ be an arbitrary coalition such that $v \not\in C$. Since $v \not\in C$ and $p_v > 0$, we have $p_C < p_{Ag} = v(Ag) = 1$. Moreover, like all coalitions, $C$ does not block $p$, so $\text{VAL}_T(C) \leq p_C$. We thus have $v(C) < 1$, and since RCRG are simple games, $v(C) = 0$.

When the grand coalition $Ag$ is losing, CNE depends on the absence of a winning coalition.

Lemma 26. If the grand coalition is losing, then the core of an RCRG is non-empty iff there is no winning coalition.
Proof. Assume $VAL_Γ(Ag) = 0$. Left to right. Let $p = (p_1, \ldots, p_n)$ be a payoff vector in the core. Since $VAL_Γ(Ag) = 0$ (Ag is losing), also $p_i Ag = 0$. Since $p$ is in the core, it is not blocked by any coalition. For any coalition $C$, we have $p_C \leq p_Ag = 0$ so $p_C = 0$. It means that for all $C \subseteq Ag$, we have $0 \geq VAL_Γ(C)$. That is, $VAL_Γ(C) = 0$ for all coalitions $C$. Right to left. Suppose there are no winning coalitions. Let $p$ be the payoff vector such that $p_i = 0$ for all $i \in Ag$. We have $pC = 0 = VAL_Γ(C)$ for every coalition $C$. So $p$ is not blocked by any coalition and it is in the core.

This would be enough to propose a working algorithm. But we can aim for an arguably cleaner algorithm, justified by the following simple lemma.

Lemma 27. If the grand coalition is losing, then there is no winning coalition iff all players are dummies.

Proof. Assume $VAL_Γ(Ag) = 0$. Left to right. Suppose $VAL_Γ(C) = 0$ for all $C \subseteq Ag$. So obviously, for every $i \in Ag$ and for every $C \subseteq Ag$, we have $VAL_Γ(C \cup \{i\}) = VAL_Γ(C)$. So all players are dummy. Right to left. Suppose that for every $i \in Ag$ and for every $C \subseteq Ag$, we have $VAL_Γ(C \cup \{i\}) = VAL_Γ(C)$. Now, let $I \subseteq Ag$ be an arbitrary coalition. We can show that $I$ is losing. Let $J = Ag \setminus I = \{j_1, \ldots, j_k\}$. A series of equalities follows: $VAL_Γ(Ag) = VAL_Γ(Ag \setminus \{j_1\}) = VAL_Γ(Ag \setminus \{j_1, j_2\}) = \ldots = VAL_Γ(Ag \setminus \{j_1, j_2, \ldots, j_k\}) = VAL_Γ(I)$. By hypothesis $VAL_Γ(Ag) = 0$. We conclude that $VAL_Γ(I) = 0$.

Lemma 25, and Lemma 26 together with Lemma 27 ensure the correctness of Algorithm 4 to decide CNE. A con-

\[\text{Algorithm 4 Algorithm for CNE}\]

\begin{verbatim}
IN: an RCRG $Γ = (Ag, G, (G_i)_{i \in Ag}, en)$
OUT: true if the core of $Γ$ is non-empty, false otherwise
1: if $(Ag$ is winning):
   2:      for $(i \in Ag)$:
   3:         if $(i$ is a veto player):
   4:            return true.
   5:      return false.
6: else:
7:      for $(i \in Ag)$:
8:         if $(i$ is not a dummy player):
9:            return false.
10: return true.
\end{verbatim}

There is a one-goal RCRG, CNE is in $\Delta_3^p$ when $LOG$ is affine $MLL$, and in $\text{PSPACE}$ when $LOG$ is affine $MALL$.

We show that deciding CNE for a class $C$ of RCRG is as hard as deciding coWIN in one-goal $C$.

Proposition 29. In one-goal RCRGs, CNE is coWIN-hard.

Proof. (sketch) Let $Γ = (Ag, G, (G_i)_{i \in Ag}, en)$ be a one-goal RCRG and let $C \subseteq Ag$ be a coalition. We build the 2-player one-goal RCRG $Γ' = (\{a\}, \{g_a, g_b\}, \{g_a, g_b\}, (en_a, en_b))$ where $g_a = \otimes_{i \in C} g_i, g_b = X, en_a = enC, en_b = \emptyset$, and $X$ is a fresh atomic proposition (not provably equivalent to 1). We can show that $C$ is not winning in $Γ'$ if the core of $Γ'$ is non-empty.
Let $p = (0, 1, 0)$ be a payoff vector. It is in the core of the game. An analysis of the (left to right) proof of Lemma 25 indicates that it is the only one.

**Discussion**

We have presented a simple, compact, and rich model of interaction for resource-conscious agents. In RCRGs, resources and goals are the same type of objects: LOG formulas. Resources can then be combined and transformed following the rules of LOG so as to yield goals. We proved with Prop. 10 that RCRGs generalise the CRGs presented in (Wooldridge and Dunne 2006), the same way that Qualitative Coalitional Games (QCG) (Wooldridge and Dunne 2004) generalise CRGs. QCGs and RCRGs on the other hand, seem to be incomparable. At least, they do not seem to have a natural formal relationship. QCGs are not compact, and rely on a characteristic function to represent the choices of the players. We could modify (extend) the RCRGs by adding such a characteristic function which would thus be an explicit representation of the choices (subsets of formulas) available to the players. Using classical logic in place of LOG, this would be sufficient to embed QCGs.

The problem WIN for CRG is NP-complete (Wooldridge and Dunne 2006). We have proved that WIN is in $\Sigma_2^P$ for MLL RCRGs (Prop. 15), but only have shown it to be NP-hard (Prop. 16) when the logic is affine. When we restrict our attention to the class of one-goal affine MLL RCRGs, the problem is NP-complete (Prop. 18). It will be interesting to determine whether WIN is in NP for MLL RCRGs.

The problem WIN is central, and instrumental for other problems. We have studied VETO, DUMMY, and CNE. The core of CRGs was also studied in (Dunne et al. 2010) but by considering CRGs as non-transferable utility games. We instead, as in Coalitional Skill Games (CSGs) (Bachrach and Rosenschein 2008), considered RCRGs as transferable utility games. In CSGs, the problem CNE is in $P$ for all the variants for which complexity results have been obtained (Bachrach and Rosenschein 2008). For one-goal MLL RCRGs, we proved that CNE is in $\Delta_2^P$ (Prop. 28) capitalizing on auxiliary algorithms for WIN, VETO, and DUMMY. We only showed, however, that the problem is coNP-hard (coWIN-hard) in Prop. 29. More work is needed in this direction.

We also have tight complexity results. Combining the results obtained in this paper, we have that:

**Theorem 30.** In one-goal affine MALL RCRG, VETO, DUMMY, and CNE are PSPACE-complete problems.

We have concentrated on one-goal affine RCRG for the algorithmic analysis of the core. Lemma 17 and Proposition 16 indicate that in the case of one-goal affine RCRGs, the problem WIN and the problem of sequent validity are inter-reducible. Our examples demonstrate that the class is already capable of representing intricate scenarios. In fact, multi-goals can be captured in one-goal MALL RCRGs using the operands $\oplus$ and $\&$: see Remark 7 and our formalization of Example 1.

For non affine RCRGs, we can provide some results, but of questionable significance. We know that WIN is in $\Sigma_2^P$ for (arbitrary) MLL RCRGs (Prop. 15). Plugging it into the algorithms that we have provided, all we can say for now is that for arbitrary MLL RCRGs, VETO and DUMMY are in $\Pi_2^P$ and CNE is in $\Delta_2^P$. No hardness results were attained.
